

## ANOVA

© Nick Lee and Mike Peters 2016.

## QUESTION 1.

You have been asked by your local sports club to compare three brands of cricket balls in relation to the distance they travel. The balls are chosen at random and are 'bowled' by a machine used during practice sessions. The distance each ball travels is recorded and shown in the table below.

| Brand A | Brand B | Brand C |
| :--- | :---: | :---: |
| 246 | 243 | 265 |
| 231 | 246 | 260 |
| 236 | 243 | 265 |
| 217 | 235 | 253 |
| 246 | 235 | 291 |

These data can be analysed using $\qquad$ factor $\qquad$ .
Construct the null and alternative hypotheses:
$H_{0}$ : $\qquad$
$H_{1}$ : $\qquad$
State three assumptions you can make:
Assumption 1: $\qquad$
Assumption 2: $\qquad$
Assumption 3: $\qquad$

Complete the following:
The variance for brand $\mathrm{A}=$ $\qquad$
The variance for brand $\mathrm{B}=$ $\qquad$
The variance for brand $\mathrm{C}=$ $\qquad$
The sum of squares between groups $=$ $\qquad$
The sum of squares within groups = $\qquad$
The total sum of squares $=$ $\qquad$
The between groups degrees of freedom, $d f_{\mathrm{b}}=$ $\qquad$
The within groups degrees of freedom, $d f_{w}=$ $\qquad$
The total degrees of freedom, $d f=$ $\qquad$
The mean sum of squares for the model, $F_{\text {test }}=\frac{M S_{M}}{M S_{R}}=$ $\qquad$
The mean sum of squares for the residuals, $M S_{R}=$ $\qquad$ $=$ $\qquad$
The value for $F_{\text {test }}=\frac{M S_{M}}{M S_{R}}=$ $\qquad$
The value for $F_{\text {stat }}=$ $\qquad$ $=$ $\qquad$
The evidence suggests that the null hypothesis should be rejected/accepted (delete as appropriate) since
$\qquad$ > $\qquad$ _.

The interpretation of this is that at least one of the $\qquad$ is different from the others.

## QUESTION 2.

The headteacher of your old school has heard that you are an expert statistician. She has asked you to help her provide some evidence that ethnicity has no impact on the mathematics attainment of year 7 pupils. You decide to look at four ethnic groups (labelled A,B,C and D in the table below) and three classes with each class having its own teacher. The table below shows the data you collected when the children were given a maths test.

|  | GP A | GP B | GP C | GP D |
| :--- | :---: | :---: | :---: | :---: |
| Teacher 1 | 4.5 | 6.4 | 7.2 | 6.7 |
| Teacher 2 | 8.8 | 7.8 | 9.6 | 7.0 |
| Teacher 3 | 5.9 | 6.8 | 5.7 | 5.2 |

Your task is find out if there is a significant difference due to the teacher and find out if the ethnicity of the child is significant.

Construct the two null and two alternative hypotheses:
Rows:
$H_{0}^{\text {row }}: \mu_{1}=$ $\qquad$ $=$ $\qquad$
$H_{1}^{\text {row }}: \mu_{1} \neq$ $\qquad$ $\neq$

Columns:
$H_{0}^{c o l}: \mu_{1}=$ $\qquad$ $-$ $\qquad$
$H_{1}^{c o l}: \mu_{1} \neq$ $\qquad$ $\neq$ $\qquad$

The row means = $\qquad$
The column means = $\qquad$
The grand mean $=$ $\qquad$
The variation of the row means from the grand mean $v_{r}=$ $\qquad$
The variation of the column means from the grand mean $v_{c}=$ $\qquad$
The total variation $v=$ $\qquad$
The random variation $v_{e}=$ $\qquad$
The row $d f=$ $\qquad$
The column $d f=$ $\qquad$
Complete the following:
For the row means at the 0.05 level of significance $F_{\text {stat }}=$ $\qquad$
The calculated $F$ value $=$ $\qquad$ -

Since $\qquad$ $>$ $\qquad$ , the null hypothesis can be accepted/rejected (delete as appropriate).
The conclusion is at the 0.05 significance level there is an signicant/insignicant (delete as appropriate) dierence in the test results due to $\qquad$
For the column means at the 0.05 level of significance $F_{\text {stat }}=$ $\qquad$
The calculated $F$ value $=$ $\qquad$
Since $\qquad$ $>$ $\qquad$ the null hypothesis can be accepted/rejected (delete as appropriate).
The conclusion is at the 0.05 significance level there is a significant/insignificant (delete as appropriate) difference in the test results due to $\qquad$ -.

## QUESTION 3.

The figure below shows the output from Excel when a two-factor experiment without replacement was carried out.

| Anova: Two-Factor Without Replication |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |
| SUMMARY | Count | Sum | Average | Variance |  |  |
| a | 4 | 24.8 | 6.2 | 1.39 |  |  |
| b | 4 | 33.2 | 8.3 | 1.29 |  |  |
| c | 4 | 23.6 | 5.9 | 0.45 |  |  |
|  |  |  |  |  |  |  |
| cr1 | 3 | 19.2 | 6.4 | 4.81 |  |  |
| cr2 | 3 | 21 | 7 | 0.52 |  |  |
| cr3 | 3 | 22.5 | 7.5 | 3.87 |  |  |
| cr4 | 3 | 18.9 | 6.3 | 0.93 |  |  |
|  |  |  |  |  |  |  |
|  |  |  |  |  |  |  |
| ANOVA |  |  |  |  |  |  |
| Source of Variation | $S S$ | $d f$ | $M S$ | $F$ | P-value | Fcrit |
| Rows | 13.68 | 2 | 6.84 | 6.24 | 0.03 | 5.14 |
| Columns | 2.82 | 3 | 0.94 | 0.86 | 0.51 | 4.76 |
| Error | 6.58 | 6 | 1.10 |  |  |  |
|  |  |  |  |  |  |  |
| Total | 23.08 | 11 |  |  |  |  |

Looking at the ANOVA table, in the box below give an explanation for each of the sources of variation (think about the grand mean):

In the box below give an explanation of $F$ and $F_{\text {crit }}$ and describe their relationship

In the box below explain what the $p$-value indicates:

The $p$-value can be used to

## QUESTION 4.

The sports club (from question 1) would now like to know which brands of cricket balls are different. What sort of test could you do to compare the means of the three brands? $\qquad$
What specific test could you use to compare the means? $\qquad$
The value of the least significant difference (LSD) statistic comparing brand A with brand B is found by:

$$
\mathrm{LSD}=t_{\alpha / 2} \sqrt{M S_{R}\left(\frac{1}{n_{i}}+\frac{1}{n_{j}}\right)}=
$$

$\qquad$
The null hypothesis is rejected if $\left|\bar{x}_{i}-\bar{x}_{j}\right|>$ LSD.

The value of the LSD statistic comparing brand A with brand C is found by:

$$
\mathrm{LSD}=t_{\alpha / 2} \sqrt{M S_{R}\left(\frac{1}{n_{i}}+\frac{1}{n_{j}}\right)}=
$$

$\qquad$
The null hypothesis is rejected if $\left|\bar{x}_{i}-\bar{x}_{j}\right|>$ LSD.
The value of the LSD statistic comparing brand $B$ with brand $C$ is found by:

$$
\mathrm{LSD}=t_{\alpha / 2} \sqrt{M S_{R}\left(\frac{1}{n_{i}}+\frac{1}{n_{j}}\right)}=
$$

The null hypothesis is rejected if $\left|\bar{x}_{i}-\bar{x}_{j}\right|>$ LSD.

## MINI PROJECT

The university you work for are looking at pre-university preparatory courses. The management are looking at two programmes: one is a 10 day condensed course and the other a 30 day course. They are also considering two delivery options: one is the programme being taught in a classroom, just like any 'traditional' programme and the other delivered on line via the Internet.

They would like you to perform a statistical analysis and advise them which option would potentially improve the courses.

You collect data from 10 randomly selected students studying on each of the programmes. The table below shows the collected data:

| Course delivery | $\mathbf{1 0}$ day | 10 day | $\mathbf{3 0}$ day | 30 day |
| :--- | :---: | :---: | :---: | :---: |
| Traditional | 26 | 18 | 34 | 28 |
| Traditional | 27 | 24 | 24 | 21 |
| Traditional | 25 | 19 | 35 | 35 |
| Traditional | 21 | 20 | 31 | 29 |
| Traditional | 21 | 18 | 28 | 26 |
| On-line | 27 | 21 | 24 | 21 |
| On-line | 29 | 32 | 16 | 19 |
| On-line | 30 | 20 | 22 | 19 |
| On-line | 24 | 28 | 20 | 24 |
| On-line | 30 | 29 | 23 | 25 |

The management want a report which will tell them if there is a statistically significant interaction between the length of course and the type of course at a 0.05 level of significance.

Your report should describe the statistical analysis technique you have chosen and why you chose to use it. It should also contain sufficient information so the management can decide from four options:

Option 1: Both courses delivered in a 'traditional' classroom.
Option 2: Both courses delivered online.
Option 3: The 10 day course delivered online and the 30 day course delivered in a classroom.
Option 4: The 10 day course delivered in a classroom and the 30 day course delivered online.

## And finally...

Interacting with statistics can be ANOVER F-test!
