Labcoat Leni's Real Research

Going out on the pierce

Problem

Guéguen, N. (2012). *Alcoholism: Clinical and Experimental Research, 36*(7), 1253–1256.

Tattoos and body piercings have become very popular since I was young. I have often contemplated having Ronald Fisher's face tattooed over my own so that people will think I'm a genius. But I digress. Research has shown that people who have tattoos and piercings are more likely to engage in risky behaviour. Nicolas Guéguen (2012) measured the level of intoxication (mass of alcohol per litre of breath exhaled, **Alcohol**) in 1965 French youths as they left bars. This measure was an indicator of risky behaviour. Each youth was also classified as having tattoos, piercings, both or neither (**Group**), and their gender was noted (**Gender**). The data are in the file **Gueguen (2012).sav**. Was the level of risk (i.e., alcohol) greater in groups who had tattoos and piercings? Did this effect interact with gender? Draw an error bar chart of the data too.

Solution

To do an error bar chart for means that are independent (i.e., have come from different groups) we need to double-click on the clustered bar chart icon in the Chart Builder (see the book chapter). All we need to do is to drag our variables into the appropriate drop zones. Select **Alcohol** from the variable list and drag it into  ; select **Group** from the variable list and drag it into  ; finally. select the **Gender** variable and drag it into  . This will mean that lines representing males and females will be displayed in different colours. Select error bars in the properties dialog box and click on  to apply them to the Chart Builder. Click on  to produce the graph.

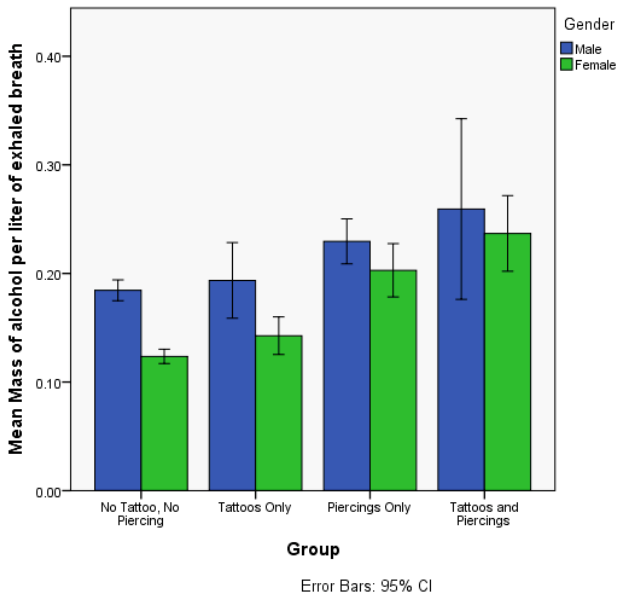

Figure 1

Figure ~~Figure 1~~ is the resulting error bar graph of these data. Looking at the graph, we can see that in each group the men had consumed more alcohol than the women (the blue bars are taller than the green bars for all groups); this suggests that there may be a significant main effect of **Gender**. There is a steady increase in the volume of alcohol consumed as we move along the **Group** variable – the *no tattoos, no piercing* group consumed the least amount of alcohol and the *tattoos and piercings* group consumed the largest amount of alcohol – suggesting that there may be a significant main effect of **Group**. This trend appears to be the same for both men and women, suggesting that the interaction effect of **Gender** and **Group** is unlikely to be significant.

We need to conduct a 4 (experimental group) × 2 (gender) two-way independent ANOVA on the mass of alcohol per litre of exhaled breath. To access the main dialog box for a general factorial ANOVA select Analyze General Linear Model Univariate... . First, select the dependent variable **Alcohol** from the variables list on the left-hand side of the dialog box and drag it to the space labelled *Dependent Variable*. In the space labelled *Fixed Factor(s)* we need to place any independent variables relevant to the analysis. Select **Group** and **Gender** in the variables list (these variables can be selected simultaneously by holding down *Ctrl* while clicking on the variables) and drag them to the *Fixed Factor(s)* box.

Descriptives

Gender				Statistic	Std. Error
Mass of alcohol per liter of exhaled breath	Male	Mean		.1909	.00442
		95% Confidence Interval for Mean	Lower Bound	.1822

	Tattoos and Piercings	-.0843*	.01544	.000	-.1146	-.0540
Piercings Only	No Tattoo, No Piercing	.0522*	.00898	.000	.0345	.0698
	Tattoos Only	.0560*	.01272	.000	.0311	.0810
	Tattoos and Piercings	-.0283	.01467	.054	-.0571	.0005
Tattoos and Piercings	No Tattoo, No Piercing	.0805*	.01255	.000	.0558	.1051
	Tattoos Only	.0843*	.01544	.000	.0540	.1146
	Piercings Only	.0283	.01467	.054	-.0005	.0571

Based on observed means.
The error term is Mean Square(Error) = .016.
*. The mean difference is significant at the .05 level.

Output 3

3. Group

Dependent Variable: Mass of alcohol per liter of exhaled breath

Group	Mean	Std. Error	95% Confidence Interval	
			Lower Bound	Upper Bound
No Tattoo, No Piercing	.154	.003	.147	.161
Tattoos Only	.168	.010	.148	.189
Piercings Only	.216	.008	.200	.233
Tattoos and Piercings	.248	.014	.220	.276

Output 4

Output ~~Output 2~~ is the output of the main ANOVA. We can see that there was a significant main effect of gender, $F(1, 1957) = 16.44$, $p < .001$, with a partial eta squared of .01. The means in Output ~~Output 1~~ (and Figure ~~Figure 1~~), reveal that men ($M = 0.19$, $SD = 0.15$) consumed a significantly higher mass of alcohol than women ($M = 0.15$, $SD = 0.11$). There was also a significant main effect of group, $F(3, 1957) = 26.88$, $p < .001$, with a partial eta squared of .04. *Post hoc* tests (Output ~~Output 3~~) revealed that participants who only had piercings ($M = 0.22$) consumed a significantly greater mass of alcohol than those who only had tattoos ($M = 0.17$) (least significant difference (LSD) test, $p < .001$) and those who had no tattoos and no piercings ($M = 0.15$) (LSD test, $p < .001$). Participants who had both tattoos and piercings ($M = 0.25$) consumed a significantly greater mass of alcohol than those who only had tattoos ($M = 0.17$) (LSD test, $p < .001$), and those who had no tattoos and no piercings ($M = 0.15$) (LSD test, $p < .001$). However, they did not consume a significantly greater mass than those who only had piercings ($M = 0.22$) (LSD test, $p = .05$).

In summary, we can conclude that individuals who have both piercings and tattoos, and those who only have piercings, consumed significantly more alcohol than those who had no tattoos and no piercings and those who only had tattoos. This effect was found in both men and women.

~~Don't forget your toothbrush?~~
